

Task Overview

You are provided with three HTML/CSS pages: **Login**, **Register**, and **Feed**. Your task is to convert these pages into a **React.js or Next.js application**, using **any backend and any database** of your choice.

You **must** use **React.js or Next.js** for the frontend. Please carefully read the features listed below. You do not need to build beyond the listed requirements, but you may add improvements if you have additional time.

Important: Stick to the **provided design**. Do not change or use any alternative design.

Features to Develop

1. Authentication & Authorization

- Implement a **secure authentication system** (session-based or JWT-based) with proper authorization.
- Registration should include: **first name, last name, email, and password**.
- No need to build features like “forgot password” or others to keep it simple.
- Users should be able to **sign up and log in** to access the feed page.

2. Feed Page

- This is a **protected route**, accessible only to logged-in users.
- All users can see posts from all other users.
- Posts should be displayed with the **most recent at the top**.
- You may ignore most of the design elements — focus only on the main functionality of the feed.

Required functionalities:

1. Ability to **create posts** with text and image.
2. Show posts with the newest **first**.
3. Display **like/unlike state** correctly.

4. Implement **comments**, **replies**, and their like/unlike system.
 5. Show **who has liked** a post, comment, or reply.
 6. Support **private** and **public** posts:
 - *Private*: Visible only to the author
 - *Public*: Visible to everyone
-

Things to Consider

1. Follow **best practices** for development, security, and performance.
 2. Use **standard database design and modeling practices**.
 3. Design the system assuming **millions of posts and reads**.
 4. **Security** and **User Experience (UX)** should be your **top priorities**.
-

Deliverables

1. **GitHub repository link** for code review.
 2. A **video walkthrough** uploaded to **YouTube (unlisted/private)**. Share the link and demonstrate your application as thoroughly as possible.
 3. If possible (recommended), **deploy the application to a live server** and provide the **live URL**.
 4. Include a **brief documentation** describing what you built and any decisions you made.
-
